On Reincarnation. Part II
The Axioms of Implicative Reincarnation

Introduction:

The aim of this work is not to define, describe, or postulate any agent that experiences reincarnation by going through birth and death. Within the scope of this work, we **do not attempt to answer** the question: **Who undergoes rebirth (reincarnation)?**

The proposed axiomatics represents a scientific and logically structured justification **of implicative reincarnation of a conditioned being** that has been born — and, as a result, must eventually die.

Key Concepts:

The first two concepts are quite clear to conscious subjects, as they relate to fundamental aspects of existence. However, it is the understanding of their interrelation that may be subject to distortion or misperception.

Conditioned living being (engaged in the process).

A living being that, by virtue of birth, experiences the state of life, which inevitably leads to the state of death.

Implicative connection

Implication (Latin *implicatio* — "connection") is a binary logical connective, functionally similar to the **conjunctions "if..., then...".** A proposition expressed through implication can also be formulated in the following ways: the premise is a necessary condition for the conclusion to occur; the conclusion is a necessary condition for the truth of the premise.

State of life (A)

Life is the consequence of the birth of a conditioned living being and is understood as the capacity to sense one's own existence. Depending on the degree of self-awareness—of which a human being may serve as an example—life means:

- experiencing the sense of “I am,”
- having the ability to act and function,
- continuously perceiving memory or its loss,
- undergoing shifts in various states of consciousness (such as the consciousness of the eye, ear, tongue, etc.).

State of death (B)

Death is understood as the cessation of the functioning of the body and consciousness of a conditioned living being. It is a state in which all biological and cognitive processes that constitute life come to an end. It is self-undefined (as an attained state), in contrast to the state of life.

Other (third) state (C)

This concept is contrary to both the state of life and the state of death, and is derived in the course of attempting to challenge the insufficiency of the implicative connection between the state of life and the state of death. In other words, it is an attempt to assert that the state of death may be followed by some third state.

The “other” (third) state encompasses the full range of phenomena, and therefore we do not distinguish a fourth state (as separate from the first two and the third), since from the standpoint of logic and scientific reasoning, they cannot be meaningfully differentiated. Thus, the category of the “other” (third) state will include all possible states distinct from the states of life and death.

Axiom 1: IF LIFE (A), THEN DEATH (B)

The premise life (A) — is a condition necessary for the occurrence of the consequence — death (B). **The consequence death (B),** in turn, represents a condition necessary for the truth of the premise itself (life can be understood as life **only in relation** to death, and to nothing else).

This axiom cannot be refuted either from the standpoint of logic or from the perspective of empirical observation, since never, nowhere, and under no circumstances has immortal, eternal life been documented — just as there is no scientific evidence that life can end in anything other than death.

Axiom 2: IF DEATH (B), THEN LIFE (A)

This axiom points **to the inseparability of the implicative connection** between the concepts of life and death, as presented in the previous axiom. This corresponds both to **logical laws and to empirical observations.**

Since, as already shown, the state of life inevitably leads to the state of death, **death can only be understood in relation to life.** There are **no logically grounded arguments** that could refute this axiom. Nevertheless, in presenting this model and demonstrating its internal consistency, we will consider **all possible counterarguments** and give them due attention.

Counterargument: “Death leads to the complete cessation of the existence of the conditioned being.”

This argument assumes that the state of death is final and does not allow for the possibility of a new birth or any form of conscious existence thereafter. According to this view, death is **the absolute cessation of the conditioned living being.** Such a perspective is characteristic of certain forms of **nihilism and atheism.**

It should be especially emphasized: within this category, **“complete cessation” implies neither rebirth** nor any form of conscious (including “afterlife”) experience. It refers specifically to a state in which neither life nor consciousness arises again, and death is interpreted as a final cessation.

Refutation

First of all,
to begin with, a conditioned living being always finds itself in the state of life (A) and never finds itself in the state of death (B) as a state of conscious experience. Death is something that can only be reasoned about from within the state of life, but not something that can be directly witnessed as a subjective experience (through direct perception).

Thus, we demonstrate that **life (A) serves as the “foundation**,” while the concept of **death (B) is a “dependent” concept** in its formation.

Consequently, life (A) functions as a first-order formal concept, whereas death (B) is a second-order formal concept. From this follows the first vulnerability of the counterargument: if the state of life, upon transitioning into the state of death, were to cease completely, it would become logically difficult to justify the initial state of life.

For if the stream is completely broken, it becomes impossible to explain where and why the next act of life arises — including the very one in which we are right now aware of ourselves as a living being.

Secondly,
if you claim that death may result in complete cessation, with no possibility of subsequent reincarnation, then you thereby break the implicative connection (A-B) between the concepts of life and death. This means you are obligated to propose an alternative logical model, within which:

- **life (A)** can still be defined as life **without being contrasted with death**,
- **death (B)** exists as self-sufficient, **without the premise of life** as its necessary condition.

The model must be consistent with empirical observations (presenting examples where eternal life has been documented, or, conversely, where death has occurred without preceding life).

Thirdly,
the model we propose is based on an axiomatics that is both fundamental and verifiable through observation of reality.

If the claim about the final and absolute nature of death had a real foundation, we would observe a steady trend toward the reduction of living beings as deaths accumulate. Considering the age of the universe (currently estimated at about 13.8 billion years), that span of time would be sufficient for the complete disappearance of life. However, the facts indicate the opposite: the number of living beings — including the human population — continues to grow.

This means that reality itself — in its observable structure — does not support the hypothesis of finality, but on the contrary, affirms the continuity and constancy of the stream of life.

Mathematical verification apparatus
A — life (initial state, self-aware and self-sufficient)
B — death (intermediate state, following life)

Axiom 1: IF LIFE (A), THEN DEATH (B)
Axiom 2: IF DEATH (B), THEN LIFE (A)

A logical structure is considered with two main propositions:
If A, then B (A → B) — denoted as:
f(A, B) = ¬A ∨ B
If B, then A (B → A) — denoted as:
g(B, A) = ¬B ∨ A

These two expressions establish an interdependence between A and B, forming a logical cycle:
A → B → A, which is logically equivalent to:
A ↔ B

Conclusion
Based on the above, we reject the argument of the finality of death as logically and empirically untenable. The model grounded in the axiomatic interrelation between life and death remains internally consistent and finds support in observable reality.

Therefore, a statement such as: **“if life, then death; if death, then complete cessation”** is unacceptable from the standpoint of logic, phenomenology, and the observable patterns of existence.

Counterargument: "Death may lead to other forms of existence, not necessarily to life"

This objection asserts that death is not necessarily the end of subjectivity or the cessation of consciousness, but may represent a transition to other forms of being.
Such states are typically cited as:

Traditional metaphysical states: heaven, hell, nirvana
Trance, altered, and transcendent states of consciousness
Astral and mental planes: subtle dimensions beyond the physical body
Worlds of immaterial entities: spirits, ghosts, gods, hungry ghosts (preta), Valhalla, etc.
Formless realms (arūpa-loka): subjectively experienced states of consciousness without form
Parallel realities and dimensions: multiverse hypotheses (Everett), alternate scenarios (DC, Marvel)

According to this position, death is **not cessation but a transition into another ontological moda**lity, which may preserve subjectivity but is not necessarily defined as "life" in the conventional biological or phenomenological sense.

Despite the fact that many of the states listed above phenomenologically resemble life (they involve subjectivity, perception, response, a structure of "self" and "world"), within the framework of this counterargument they are regarded as distinct from the state of life (A). This is a key point: the counterargument claims that all forms of being—except life itself (A)—are possible after death. In other words, it allows for the existence of everything except a return to life (A), from which the being is said to have departed completely and irreversibly.

Thus, the very structure of the argument is not aimed at affirming the diversity of forms of existence, **but at excluding a single state — life (A).**

Refutation

The concept of the **"other" state (C)** has already been presented earlier in the section on key concepts and **does not require further clarification** in the context of this counterargument.

Since the conditioned living being first experiences **life (A)**, and then **death (B**), any claim about the possibility of **other forms of existence (C)** after death requires acknowledgment of **a continuous connection** between these states.

If we assume that prior to birth the conditioned being existed in some "other" state (C), but has neither memory nor any conception of it, then such a state lacks phenomenological significance, and the concept can be reasonably excluded from the discussion.

Moreover, the mere assumption of the existence of an "other" state (C) is not supported by empirical data and cannot be recognized as logically justified, since it is introduced post hoc in an attempt to assign uniqueness to the "other" (third) state, which in its structure is a third-order formal concept.

State (C) is logically unstable and cannot be considered a self-sufficient foundation within the context of the implicative model of existence. Moreover, if death truly leads to some "other" state, then it is necessary to:

- **demonstrate a continuous connection (A–B)** between life and death, and simultaneously a **continuous connection (A–C)** between life and the "other" state;
- or justify a **mechanism by which the connection (B–C) somehow transforms into (C–A),** that is, explain how the "other" state once again becomes linked to life.

But as previously demonstrated, such a break is impossible — **neither logically nor empirically**.

Mathematical verification apparatus
A — life (initial state, self-aware and self-sufficient)
B — death (intermediate state, following life)
C — other state (hypothetical, following death).

IF LIFE (A) → THEN DEATH (B) → THEN OTHER (C)
A third proposition is added:

- **If B, then C (B → C)** — denoted as:
  h(B, C) = ¬B ∨ C

Verification:
If A = True, then from the axiom A → B it follows that B = True.
From B → A, it again follows that A = True. → Thus, a logical cycle A ↔ B is formed.
If further from B → C it follows that C = True, this has no effect on the truth of A or B, → therefore, C is logically independent of the closed pair A ↔ B.

The connection (A–C), prior to the occurrence of the state of death (B), is neither justified nor empirically supported, just as the mechanism of forming such a connection (C–A) after death (B) is not established.→ Therefore, (C) is logically redundant and does not belong to the necessary structure.

Mathematical justification of transitivity:
If A → B and B → C, then A → C. However, since A ↔ B, C becomes insignificant, as the entire logic is closed upon A.

Logical conclusion in the context of interpretation:
If A → B and B → C, then A → C.
However, since A ↔ B, C becomes insignificant, as the entire logic is closed upon A.

Life (A) entails death (B), Death (B) entails life (A). This creates the equivalence: A ↔ B.
Life remains the initial and defining point. The other state (C) does not affect this connection, as it is not experienced consciously like life and does not alter its essence.

Conclusion
Based on the above, the counterargument regarding the possibility of other forms of existence (C) after death (B) lacks empirical support and does not withstand logical scrutiny. Our axiomatics remains internally consistent and is confirmed by the stable implicative connection between life (A) and death (B). Therefore, this argument is rejected as logically and phenomenologically untenable.

Counterargument: «The state of death leads to the state of death»
Although this is merely a tautology, this counterargument is important to consider.

Refutation

If the state of death led only to itself, there would be no logical possibility of justifying the state of life as fundamentally present. Moreover, the implicative connection between the two states (life → death → life) would be rendered invalid.

Moreover, to logically claim that the state of death transitions into the state of death is equivalent to saying that something transitions — yet no actual transition occurs, since there is no shift from one state to another within a single concept. This is not the case, however, when the state of death is followed by a return to the state of life.

Such a counterargument represents an absurd construction reducible to the concept of “the death of death,” and is nothing more than an attempt to assign death the status of self-existence — that is, existence independent of life. This claim is rejected as logically unsound, empirically unsubstantiated, and in direct contradiction to the first axiom.

Conclusion

Thus, the concept of "self-sufficient death" does not withstand either theoretical or observational scrutiny, and **is therefore dismissed as absurd**.

Axiom 3: IF LIFE (A), THEN LIFE (A)

Life (A) is the initial, self-aware, and self-sufficient point. All intermediate states — **death (B)**, the hypothetical **“other” (C)**, or even complete cessation — lack substantial significance, as they are not consciously experienced and do not disrupt the identity of life as an act of self-experience.

The implicative structure emphasizes: life always returns to itself, preserving continuity and essential self-identity: **A → A**

Mathematical verification apparatus

A — life (initial state, self-aware and self-sufficient)
B — death (intermediate state, following life)
C — other state (hypothetical, following death).

Reduction of implication (excluding B):

The following hypothesis is considered: whether B can be logically excluded by reducing the system to **A → A**. Since **A → B and B → A**, it follows that **A ↔ B** (interdependence). Consequently, the system reduces to **A → A** — a tautology that is always true and internally consistent.

Thus, B contributes no new information and can be excluded from the structure. The system A → B, B → A, B → C shows that B and C can be eliminated — everything reduces to A → A. Life (A) is the only meaningful state to which everything returns. Boolean functions confirm that C has no effect on the truth of the system, and the implication reduces to A → A.

Phenomenological illustration:

Even if I have existed in millions of other states, including those that may have followed death, I find myself once again in life. Even without remembering what I may have gone through, the very fact of discovering myself in the state of life indicates that life returns to itself, and any other states—if they occurred—are not retained as valid within subjective experience.

Conclusion

This argument emphasizes that **life and death are in an inseparable implicative connection,** and the very fact of consciousness reappearing in life — even after the **absurd notion of an “other” state — serves as the strongest confirmation of the cyclic nature of being and the continuity of the living stream of existence.**

Namaste!
